Github Repository at https://github.com/ThomasBolden/PHY-480-Spring-2016

Abstract

In this project, a solution was found to the two-electron Schrödinger equation in three-dimensions. This was done by diagonalizing an n by n matrix to find the eigenfunctions and eigenvectors of the three lowest energy states. Computation time to determine the eigenvalues was compared between a brute-force implimentation of Jacobi's algorithm and the Armadillo library. For large n, the Armadillo library is orders of magnitude faster. Using the Armadillo *eig_sys* function, the wavefunctions of the lowest three energies are compared while varying the strength of the harmonic oscillator potential.

Introduction

In physics, there is a known solution to Schrödinger's equation for a single electron in a spherically symmetric three-dimensional well. However, this equation becomes more complicated when another elctron is added. In addition to the energy term, there are Coulombic interactions between the electrons that must be accounted for.

For one electron, the radial part of the Schrödinger equation reads

$$-\frac{\hbar^2}{2m}\left(\frac{1}{r^2}\frac{d}{dr}r^2\frac{d}{dr}-\frac{\ell(\ell-1)}{r^2}\right)R(r)+V(r)R(r)=ER(r)\ \ ,\ \ V(r)=\frac{m\omega^2r^2}{2}.$$

In this case, the potential function for the harmonic oscillator is $V(r)=\dfrac{m\omega^2}{2}$, and E is the 3D energy. With th quantum numbers n and l, the energies are given by

$$E_{nl}=\hbar\omega\left(2n+l+\frac{3}{2}\right).$$

If we are to solve this computationally, it is helpful to introduce a dimensionless variable $\rho=1/\alpha$, with α is the length constant.

$$-\frac{\hbar^2}{2m\alpha^2}\frac{d^2}{d\rho^2}u(\rho)+\left(V(\rho)+\frac{l(l+1)}{\rho^2}\frac{\hbar^2}{2m\alpha^2}\right)u(\rho)=Eu(\rho)$$

If we neglect angular momentum by setting $l=0$, and making $\omega=\alpha\rho$, we get

$$-\frac{\hbar^2}{2m\alpha^2}\frac{d^2}{d\rho^2}u(\rho)+\frac{k}{2}\alpha^2\rho^2u(\rho)=Eu(\rho)$$

If both sides of the equation are multiplied by $\dfrac{2m\alpha^2}{\hbar^2}$ and fixing $\alpha=\left(\dfrac{\hbar^2}{mk}\right)^{1/4}$ the equation becomes

$$-\frac{d^2}{d\rho^2}u(\rho)+\rho^2u(\rho)=\lambda u(\rho).$$

Discrete energy eigenvalues are given by

$$\lambda=\frac{2m\alpha^2}{\hbar^2}.$$

The first three eigenvalues are the $\lambda_0=3$, $\lambda_1=7$, $\lambda_2=11$.

In order to solve this, the standard approximation of the second derivatve with step length h,

$$u''=\frac{u(\rho+h)-2u(\rho)+u(\rho-h)}{h^2}+O(h^2),$$

will be used. The finial tridiagonal matrix is then

$$\begin{pmatrix}
\frac{2}{h^2}+V_1 & -\frac{1}{h^2} & 0 & 0 & \dots & 0 & 0\\
-\frac{1}{h^2} & \frac{2}{h^2}+V_2 & -\frac{1}{h^2} & 0 & \dots & 0 & 0\\
0 & -\frac{1}{h^2} & \frac{2}{h^2}+V_3 & -\frac{1}{h^2} & 0 & \dots & 0\\
\dots & \dots & \dots & \dots & \dots & \dots & \dots\\
0 & \dots & \dots & \dots & \dots & \frac{2}{h^2}+V_{n_{\text{steps}}-2} & -\frac{1}{h^2}\\
0 & \dots & \dots & \dots & \dots & -\frac{1}{h^2} & \frac{2}{h^2}+V_{n_{\text{steps}}-1}
\end{pmatrix}.$$

In this project, I explore and compare various ways to solve the two-electron Schrödinger equation. In the following section, the methods used to write and impliment the Jacobi rotation code are discussed. In the Results section, I present the data I have found. I discuss it in some detail, but most of the analysis is saved for the Conclusions section. Finally, the Code section is a collection of the code used to produce the results.

Methods

The general algorithm for Jacobi's rotation is as follows:

Update !! !!!!!!!!!!!!!!!!!!!!!!!!!!!!

Algorithm 1 Jacobi Rotation

1: **procedure** J(a)cobi Rotation
2: $n \times n$ matrix A
3: **function** M(a)xOffDiagonal
4: **end function**
5: **end procedure**

When implimenting this algorithm, it is important to choose the smaller magnitude solution to $t = -\tau \pm \sqrt{1+\tau^2}$. To get a sense of why, it is best to use the equation

$$\left\|\mathbf{B}-\mathbf{A}\right|\Big|_F^2 = 4(1-c)\sum_{i=1,i\neq k,l}^{n}(a_{ik}^2 + a_{il}^2) + \frac{2a_{kl}^2}{c^2}.$$

This equation, with $c = \dfrac{1}{1+t^2}$, gives the difference between matrices **A** and **B**. Since we want to minimize this difference, it becomes clear that we want to take a value of c to be as close to 1 as possible. Doing this will make the $(1-c)$ term go to zero. Since we want a value of c that is close to one, the t value chosen must be as small as possible. This is because of the way c is defined above. With small t, the denominator approaches 1, allowing c to also approach 1.

Results

When the dimensionality of the matrix is changed, the dimensionless variable ρ needed to accurately determine the lowest three eigenvectors also changes. The data is graphed in Table 1, and graphed in Figure 1.

Table 1: Checking ρ Dependency for Various Matrix Dimensionality

Minimum $\rho_{\max}$	Matrix Dimensions n
5	200
6	250
7	300
8	350
9	400
10	450

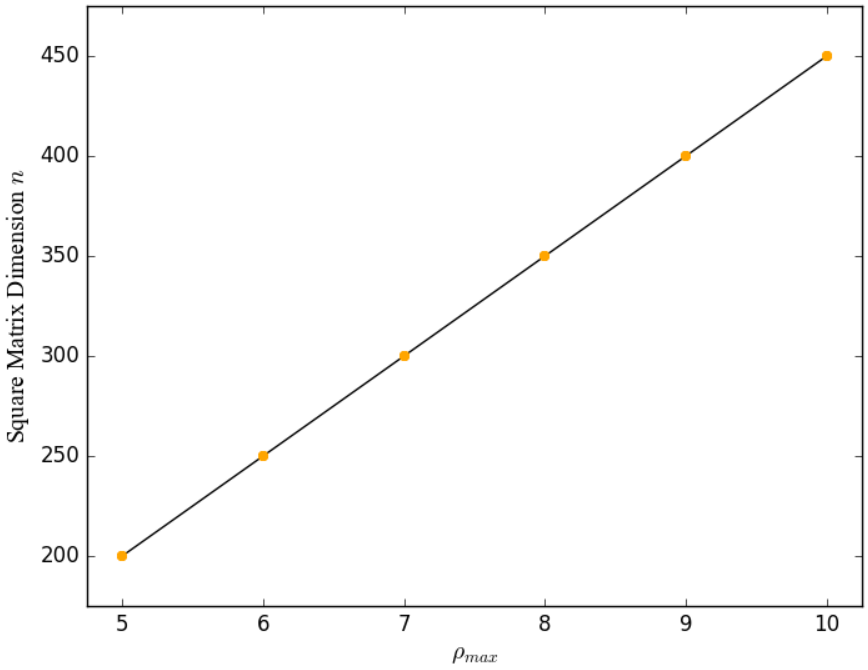

Figure 1: Value of ρ Required for Accurate Eigenvalues

With a step size of 50 for the matrix dimensinality, the relationship between ρ and n is perfectly linear.

Using this fact, one can test the number of similarity transformations required to effectively diagonalize the matrices. Implimentation of `EigensolverTests.cpp` gives these results. Here, the tolerance for a nondiagonal matrix element was set to $\epsilon = 1 \times 10^{-10}$. The number of transformations required to diagonalize a square matrix of dimension n are listed in Table 2. The computation times are also compared between Jacobi's algorithm and Armadillo's library.

Table 2: Comparing Jacobi's Algorithm to Armadillo Using $\rho = 5.0$

Dimensionality n	Eigenvalues	$t_{\text{Armadillo}}$ (s)	t_{Jacobi} (s)	Transformations
50	$(2.99687, 6.98434, 10.9619)$	0.000617	0.08572	4139
100	$(2.99922, 6.99609, 10.9907)$	0.003777	1.15983	17293
150	$(2.99965, 6.99827, 10.9960)$	0.007561	5.89020	39377

450	$(2.99996, 6.99981, 10.9997)$	0.094821	901.509	361794
500	$(2.99997, 6.99985, 10.9998)$	0.123586	1394.52	447415

From this data, the number of transformations based on the dimensionality of the matrix was graphed. The curve was fit quadratically using *polyfit* from the numerical python library. The graph and its equation are shown in Figure 2.

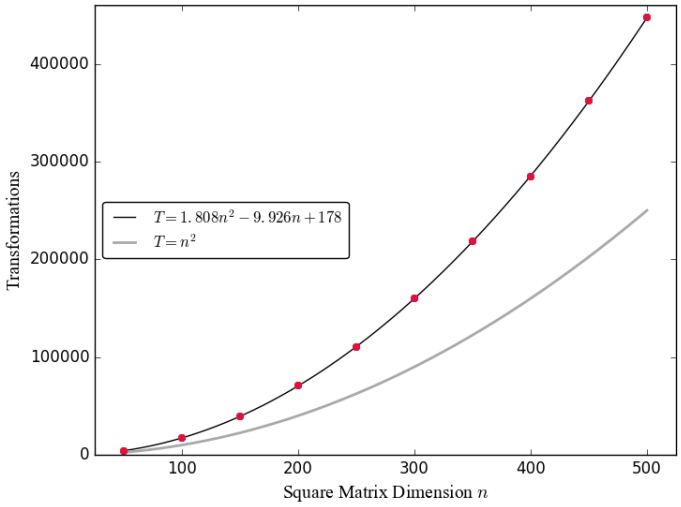

Figure 2: Tansformations Increasing with Dimensionality

The next task was to plot the two-electron wavefunctions as a function of the relative coordinate ρ and varying values of ω_r. In the figures that follow, the two-electron wavefunctions are plotted as probability distributions. Four values for ω_r were used and compared. They are: $\omega_r = \{0.01, 0.50, 1.00, 5.00\}$. The wavefunctions assumed the electron in the ground state, with $l = 0$. The first three eigenvectors graphed were found using Armadillo's *eig_sys* function.

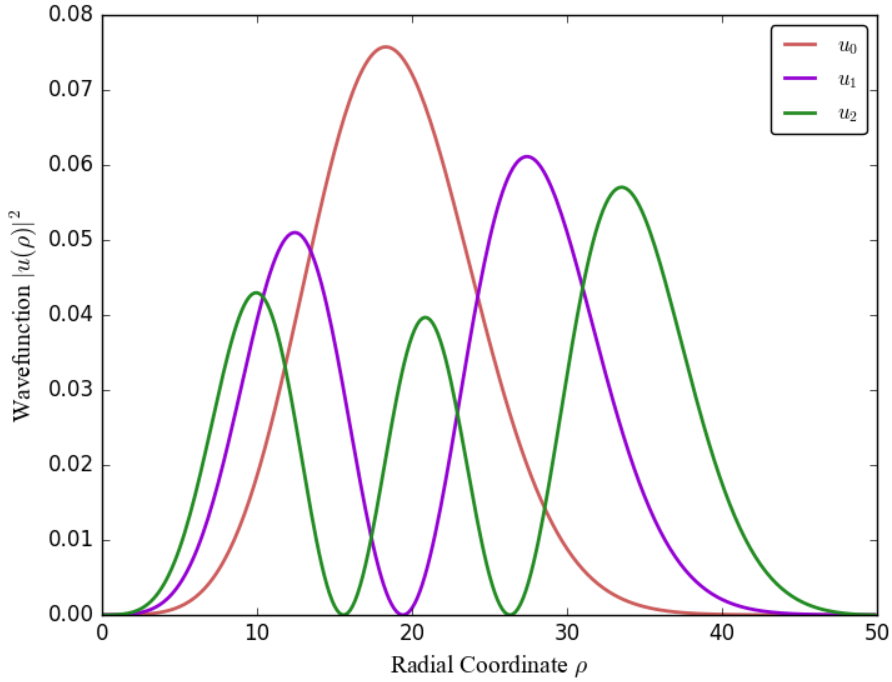

Figure 3: Wavefunction with $\omega_r = 0.01$

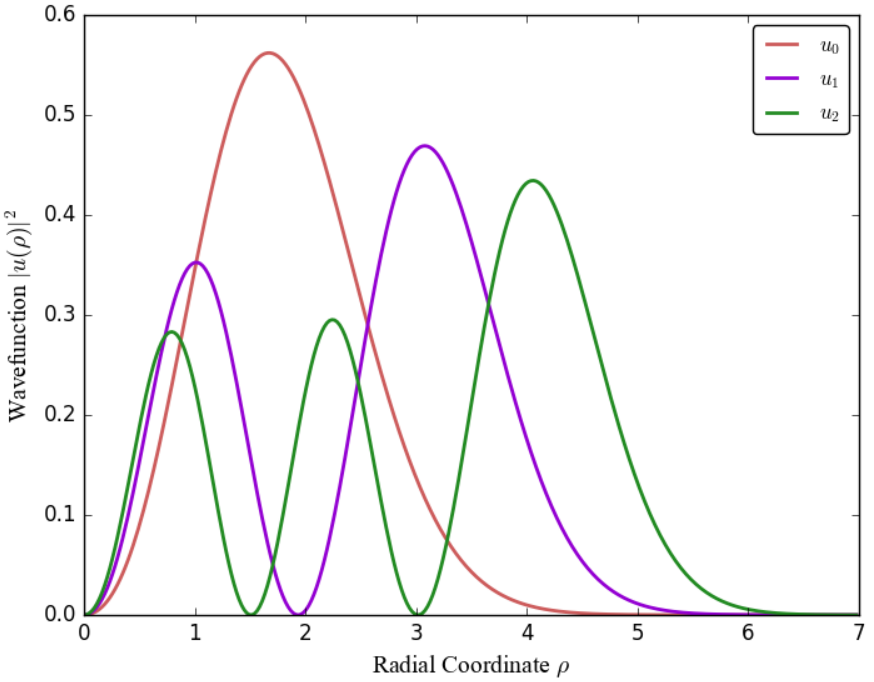

Figure 4: Wavefunction with $\omega_r = 0.50$

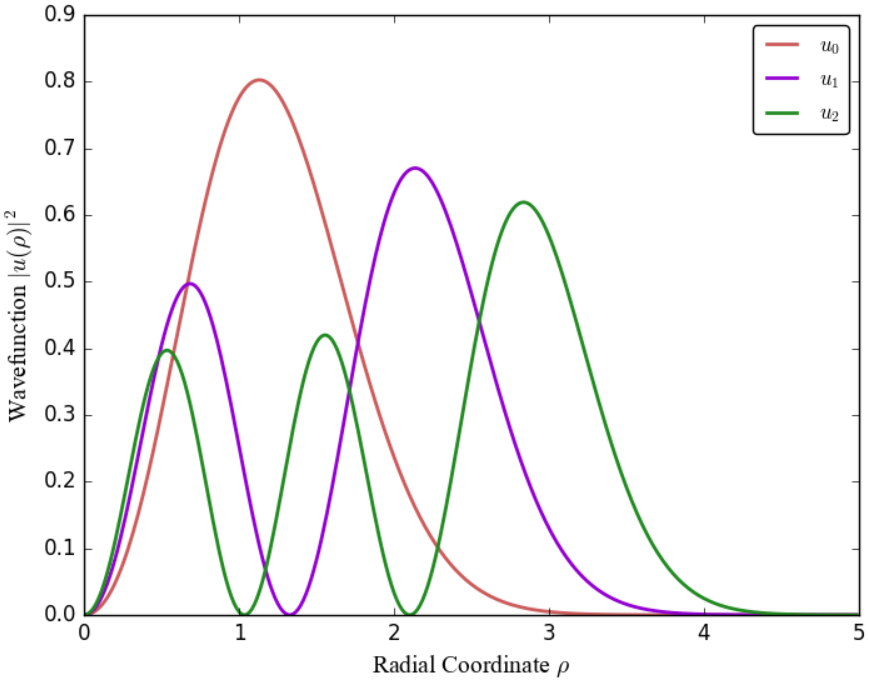

Figure 5: Wavefunction with $\omega_r = 1.00$

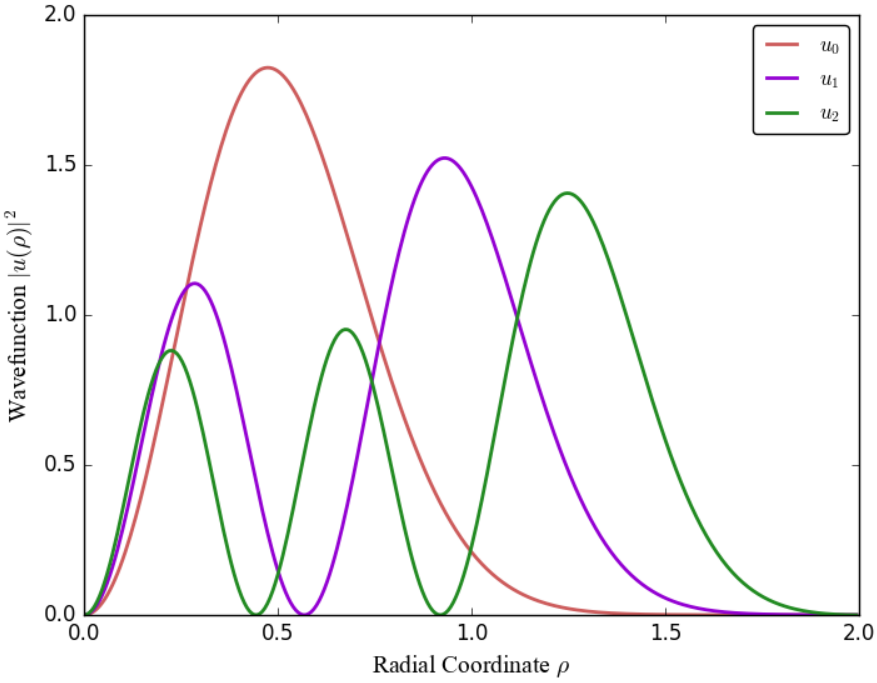

Figure 6: Wavefunction with $\omega_r = 5.00$

Conclusions

The first task was to impliment algorithms that solve a one electron system in a three dimensional harmonic oscilator potential well. To do this, a square matrix was diagonalized using both a brute-force Jacobi rotation algorithm and Armadillo. Jacobi's method for diagonalizing matrices was found to be orders of magnitude slower than the Armadillo library's *eig_sys* function. This means that, while useful and simple to impliment, Jacobi's method is only practical for small matrices.

The next task was to compare the transformations required to diagonalize a matrix based on its dimensionality. The transformations seemed to scale as nearly the square of the dimensions.

The final task was to use the most efficient and accurate settings for $\rho_{\max}$ and n, and extend it for the two-electron model. The wavefunctions were tested with varying oscillator strength (ω_r), and it was found that the relationship between ω_r and the wavefunction spread across ρ was inverse. In other words, as ω_r increased, the wavefunction compressed.

All in all, both Jacobi rotation and Armadillo are accurate methods to diagonalize matrices. However, in order to be useful, the program must also be efficient. So, if one is to use either of these methods in the future, brute-force Jacobi rotation is not fast enough, and the Armadillo library is much more reasonable.

~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
        Project 2 - Schrodinger's Equation for two electrons in
                    a three-dimensional harmonic oscillator well

        Part d)   - Solving the 2-electron wavefunction of coordinate
                    rho with varying omega_rho

                    This program reads text files with normalized
                    eigenvectors as a function of rho and graphs
                    the normalized dimensionless wavefunctions.

                    Adjust the name of the file and graph as needed

                    Wavefunctions are graphed and saved to png.
